

The Water Cycle

This starts with the energy from the S_____ heating the water on Earth. The water is in the rivers, the S_____ and the lakes and even the puddles!

When water heats up, the moisture rises up into the air and this process is called e_____.

Then the moisture all moves together to form cl_____, this is called c_____.

The clouds hold the water, until they are too full and heavy to stay together and then it falls as r_____, the scientific word for this is pr_____.

This water then runs down hills and slopes until it joins the r_____ and s_____ again. This is called run off.

The water then evaporates again. Water keeps going around in this circle all the time, between land, air and sea, but the actual amount of water on Earth never changes!
